

— AGRICULTURAL COMMERCE PLATFORM

One connected marketplace for everything after harvest.

A production-style PHP and MySQL platform designed to connect Balochistan's farmers, buyers, cold-storage operators, and transport providers through transparent, role-aware digital workflows.

PREPARED BY

Zubair Ahmed

PLATFORM

Web · PHP · MySQL

PROJECT STAGE

Commercial MVP

01

— BUSINESS PROBLEM

Agricultural trade is fragmented after the crop leaves the farm.

Farmers and buyers often coordinate produce, pricing, storage, and delivery through disconnected channels. That fragmentation makes commercial decisions slower, records harder to trace, and available services more difficult to discover.

Limited market access

Growers need a structured way to publish available produce, while buyers need consistent discovery by crop, grade, origin, quantity, and price.

Weak price visibility

Scattered reference prices make comparison difficult and reduce confidence when farmers and buyers negotiate commercial terms.

Post-harvest coordination

Cold-storage capacity and transport availability are separate operational problems, increasing the risk of delays and product deterioration.

Low workflow traceability

Informal messages and manual follow-ups provide limited visibility into offers, orders, bookings, delivery stages, and responsibility.

CORE OPPORTUNITY

Bring discovery, negotiation, storage, transport, and accountable status records into one locally relevant platform—without pretending that unconfigured payment or external delivery services already exist.

02 · PROPOSED SOLUTION

A role-aware digital trade desk for the complete post-harvest journey.

Quetta AgriLink combines a public agricultural marketplace with protected workspaces, lifecycle records, local market intelligence, cold-storage discovery, and transport coordination.

TECHNICAL FOUNDATION

PHP 8+

MySQL / MariaDB

PDO

Vanilla JavaScript

Protected AJAX

XAMPP

03 · DELIVERY PERSPECTIVE

AI-assisted execution, guided by product judgment and technical validation.

The project used AI tools to accelerate exploration and implementation. Architecture, feature selection, security boundaries, testing, and final decisions remained part of the developer's review process.

AI tools used

M

Manus AI

Supported early-stage exploration and helped turn a broad agricultural marketplace idea into a structured product direction.

- Requirements organization
- Feature and workflow ideation
- Initial project planning support

AI

ChatGPT

Assisted throughout implementation and refinement as a collaborative coding, debugging, and design-review tool.

- PHP, SQL, CSS, and JavaScript assistance
- Debugging and edge-case analysis
- Interface copy and usability refinement
- Validation and test-scenario support

Responsible use: AI output was reviewed, adapted, and validated before inclusion. Sensitive business actions continue to rely on server-side rules and database records.

Challenges faced

1

Designing for five distinct roles

Each role required focused permissions and dashboards without fragmenting the experience into separate products.

2

Maintaining trustworthy workflow state

Offers, orders, storage bookings, and transport requests needed controlled transitions and permanent history.

3

Protecting ownership and actions

Role checks, record ownership, prepared statements, CSRF protection, secure sessions, and output escaping had to work together.

4

Keeping one coherent design language

Public pages, authentication, role dashboards, responsive navigation, alerts, and dense operational tables needed one professional system.

5

Aligning schema and migrations

A growing normalized database required careful reconciliation between fresh-install SQL and incremental migrations.

6

Respecting production boundaries

The local MVP had to remain honest about unconfigured external support, password delivery, live market data, and regulated payments.

PROJECT OUTCOME

A unified, responsive agricultural commerce application with role-based dashboards, secure transactional workflows, local support, notifications, market-price records, storage discovery, and transport coordination—built as one maintainable PHP/MySQL codebase.
